# **1.0 Introduction: All Unit types and All Vehicle Defect Types**

## 1.1 C101 Causal Unit Type

The high level analysis of vehicles in general for vehicle defects showed a high correlation of the defect type and the vehicle type, which is expected since certain defects apply only to trucks and other specialized vehicles. The Causal Unit analysis given immediately below establishes that: (1) the most over-represented vehicles are heavy trucks (as we might expect), but (2) the highest frequency is in the Passenger Cars and SUVs, which are the most UNDER-represented.

<u>  </u>					C101· C	ausal Unit (	CU) Type					

The display above shows that Passenger Cars and SUVs are getting the highest number of vehicle defect crashes, not because they have more defects per vehicle, but because of their sheer number on the roadway. This is demonstrated by the under-representation of Passenger Cars and Sport Utility Vehicles (SUVs) when they are compared to the same vehicles without defect-caused crashes. Another very common passenger vehicle, that, in this case, is shown to be over-represented in vehicle-defect crashes is Pick Up trucks (second from the top).

#### 1.2 Listing of <u>All C222 CU Contributing Vehicle Defects</u>

The above display is in Subset Frequency order. The Other Frequencies are all 0 indicating that there are no vehicle-defect caused crashes in the Other Frequency (i.e., the control) subset. Clearly, Brakes (6,539) and Tires (3,493 + 1,668 = 5,161) are the two highest frequency vehicle defects, and these will be given concentrated study below. This does not mean that other defects should be ignored. Each individual vehicle should be reviewed in terms of all of it potential defects to determine how to best maintain it so as to reduce these crash causes.

#### **1.3 Filters for the Analyses**

The results above led to the decision to separate the most common passenger vehicles from large trucks in Sections 2 and 3 below. Considering the passenger cars simultaneously with the large trucks would produce ambiguous results. To solve this problem, two separate runs were performed, where the subdivision is based on C101 - CU Unit Type. Specifically, the display below indicates how Large Trucks with vehicle defects were defined for this study. The details for this analysis is given in Section 2.

The goal of both analyses was to determine the other attributes given on the crash reports that are correlated with vehicle defects. These are given in the Table of Contents for Sections 2 and 3 above. Each of the analyses will start out with a summary of the Causal Unit (CU) vehicle defects themselves (C222 CU Contributing Vehicle Defect). This is followed by IMPACT analyses on a number of attributes that were considered to be relevant.

# 2.0 Large Truck Analysis

#### 2.1 C101 Causal Unit (CU) Type Analysis When Large Truck Involved

This comparison is between vehicles with defects against the same type units without defects, restricted to crashes that involved the respective large trucks (on both sides of the comparison). Most of the two-vehicle crashes involve a passenger car, since truck-truck crashes are relatively rare. The following display indicates the vehicle type for each defective vehicle type that <u>caused</u> the crashes. The assumption is that the recording officer would not indicate a vehicle defect for a vehicle if that vehicle did not cause the crash.

The output above is ordered by Max Gain, which considers both the number of crashes in which the unit caused (the first numerical column) and the over-representation (as measured by the Odds Ratio). The Max Gain is the number of crashes that would be eliminated if there was some countermeasure implemented that could cause its Subset Percent to be the same as the control (Other Percent). For example, in the first item list, which has a causal frequency of 947 crashes,

102 of these could be eliminated if the effect of vehicle defects were eliminated (making the value in the Subset Percent list to be 50.95). This list enables motor-carrier professionals to determine which vehicle types need the greatest emphasis when it comes to reducing their vehicle defects.

We will continue with the IMPACT results that had the highest total Max Gains, and also those with the most practical significance.

#### 2.2 C222 CU Contributing Vehicle Defect by CU Unit Type Cross-tabulation

The cross-tabulation below shows what defects this analysis is considering; and it answers the question of: in general, what vehicle defects are included in the analysis given above. This is a cross-tabulation of C101 (Vehicle Type) by C222 (Vehicle Defect) for the large truck study.

CARE 10.2.1.3	- [Crosstab Results	- 2017-2021 Alabar	na Integrated Crasl	n Data - Filter = Veh	Def CU Hvy Trk C2	22]			- 0	X

E Body/Doors	8	3	2	0	6	0	0	3	22	
TOTAL	303	181	148	18	947	22	2	37	1658	1

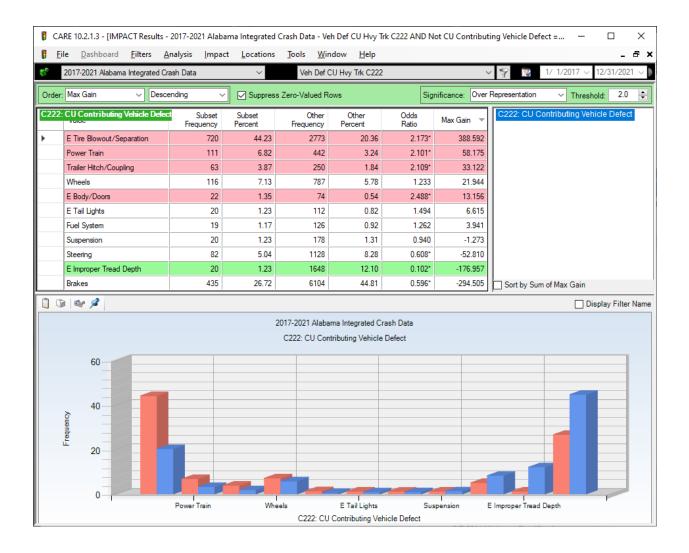

For some examples, brakes are more of a problem with both types of single-unit trucks than with other truck types, with the exception of Tractor/Semi Trailer, which has almost half of the Brakes total frequency.

#### 2.3 Large Truck Defect Crashes (LTDC) Compared Non-LTDC

The displays that follow compare Large Truck Defect Crashes (LTDC) against all crashes that were not LTDC independent of their vehicle type or whether defects were involved in the crash (henceforth called Non-LTFC).

## 2.3.1 C222 Causal Unit Vehicle Defect in LTDC vs Non-LTDC

The display below gives the distribution of the vehicle defects that occurred in the vehicles given in the defects analysis in Section 2.1. The table indicates that Tire Blowout/Separation is the highest frequency (720), followed by Brakes (425, under-represented), Wheels (116). and Power Train (111). following. Apparently Improper Tread Depth is not as large a problem for large trucks as it is for passenger cars. We expect this is because of the continual inspections given to large trucks by FMCSA and the ALEA Motor Carrier unit.

				0	219: CU Attachme	ent		

The CU Attachment display above tends to indicate the causal vehicle use. For the Subset Frequencies, the causal vehicle would, except in rare cases, have the vehicle defect. The above comparison is Large Trucks with Defects Crashes (LTDC) against both large trucks without defects and all other vehicle types whether they had defects or not (Non-LTDC). As an example, Log Trailers (third attachment listed) had 6.03% of the LTDC crashes, but only 0.14% of all of the other vehicle crashes (Non-LTDC), creating an extremely large odds ratio (41.878). The Max Gain of 97.612 crashes represents the number that could be reduced if the over-representation was eliminated (i.e., the Odds Ratio somehow was forced to be 1; reducing the 6.03% to its expected value of 0.14%.

#### 2.4 C052 Number of Vehicles

Single vehicle crashes are over-represented, in the Large Truck Defect Crashes (LTDCs) as are all multi-vehicle crashes with three or more vehicles. Two-vehicle crashes are under-represented with 0.633 of the proportion that occurs in Non-LTDCs. The Odds Ratio indicates that single vehicle crashes occur over twice (2.138) their expected proportion. These results are quite similar to those for passenger cars (Section 3.3).

			0.011	C019: E Mo	ost Harmful	Event			

The display above was trimmed to exclude all events that had less than ten occurrences. Red in the tabular background portion of the output indicates that that the Harmful Event had an over-representation for LTDCs of at least twice its expectation (odds ratio > 2) when compared to crashes for that harmful event that were Non-LTDC. Green in the background indicate an under-representation of 0.500 or less. Clearly there are many Most Harmful Events whose probabilities of occurrence are greatly increased by vehicle defects.

#### 2.6 C023 Manner of Crash

For two-vehicle crashes, this gives an idea of how the two vehicles came together. But note that a large plurality of crashes (37.76%) were single vehicle, much higher than the 19.54 expected compared to the Non-LTDC crashes. The same over-representation of LTDCs holds for the Non-Collision category. An example of Non-Collision might be where a defective tire caused a vehicle to run off the road and the incident was reported even though no collision with another vehicle or other obstacle resulted.

#### 2.7 C011 Highway Classification and Speeds

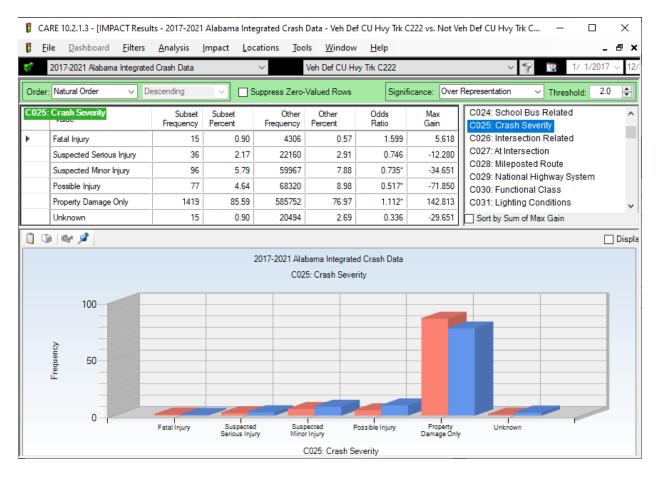

All other things being equal, it is expected that each Highway Classification will have the same proportion of LTDC crashes as the defective vehicle-miles traveled on it over the course of the study. In this case, Interstates probably have over twice the traffic of vehicle-miles (in this case by large trucks) that might have vehicle defects. So the over-representation on Interstate highways is reasonable. Also, tire blowouts tend to occur at higher speeds, which would favor Federal and State routes over County and Municipal. Note the speeds of blowouts shown in the following cross-tabulation of impact speeds by vehicle defect.

# 2.8 Cross-tab of C224 Impact Speeds by C222 Defect Type for LTDC Vehicles

Tires blow out more frequently at the higher speeds, since this puts additional stress on tires. Brakes and Steering tend to go out at any speed, since they are more evenly distributed across the impact speed range.

# 2.9 C025 Crash Severity

Crashes involving large trucks that were caused by vehicle defects have a larger proportion of fatal crashes (0.90% for LTDCs as opposed to 0.57 for all other vehicle crashes). No definitive conclusions can be drawn, however, with such a small sample (15 fatal crashes). The other three injury classifications are under-represented, and PDO crashes are significantly over-represented. It is possible that in many cases drivers can sense when there is a vehicle defect, and they slow down or stop to address the problem. Even if they only reduce speed in anticipation of a potential problem, this can dramatically lower the severity of the crash or chances of a fatality. Other studies have shown that the probability of a fatality is approximately cut in half for every 10 MPH reduction in the impact speed.

					C208: CU Mo	del Year		

The age of the vehicle would definitely impact its chances for its containing defective components. The model years begin to be significantly over-represented in 1998, and this continues through 2000, after which they generally become under-represented up until 2016. From that model year and above there seems to be more vehicle defect crashes than would be expected from a comparison with the Non-LTDC subset.

# 3.0 Passenger Vehicle Analysis

#### 3.1 C101 Causal Unit (CU) for Passenger Vehicles Involved

The filter used to perform this study required that a passenger vehicle under consideration in the Subset Frequency list was the Causal Unit. Large trucks were not excluded from consideration in the control group, but unlike the analysis above, there was no requirement for the presence of a large truck in the crashes being considered in the Subset. See the Introduction (Section 1.0) above for a formal definition of the particular vehicle types that had to be involved to qualify for these analyses. Note that the Display Filter Name will be turned on for all IMPACT analyses that are not pruned. Pruning is made obvious when all of the Cxxx attributes except the particular one selected appear in the attribute choice list (column to the extreme right of the display).

As is true of most of the IMPACT analyses, the above display is listed out in order of Max Gain. While pick-up trucks have the highest Max Gain, Passenger Cars have over twice the frequency. Despite their over-representation, Pick-ups account for less than a quarter (24.13%) of the LTDC crashes. The combination of pick-ups and passenger cars adds up to over 10,000 crashes (about 75%), and most of the rest are Sport Utility Vehicles (SUV).

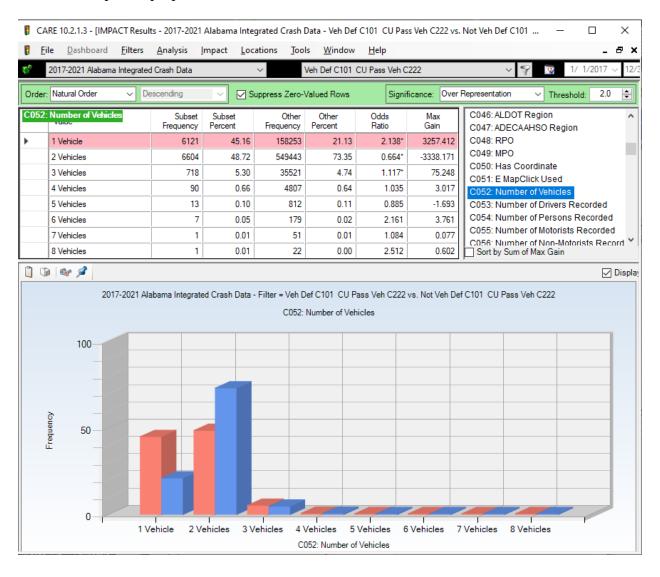

#### 3.2 C222 CU Contributing Vehicle Defect

Per-vehicle-type defect analyses are easily obtainable by a cross-tabulation of C101 by C222. The following is the example for passenger vehicles and vehicle defects. It is interesting that some cells with only one crash are still higher in proportion than the summary value, and thus have a red background. It is clear that brakes and the two tire defects produce the largest numbers. We will see below that tire problems eclipse the braking issues when it comes to causing fatalities.

#### 3.3 C052 Number of Vehicles

This attribute plays a large role in many of those discussed below. Single vehicle crashes are over-represented, as are all multi-vehicle crashes with three or more vehicles, except that of five vehicles. Two-vehicle crashes are under-represented with 0.664 of the proportion that occurs in non-vehicle-defect crashes. The Odds Ratio indicates that single vehicle crashes occur over twice their expected proportion.

# 3.4 C019 Most Harmful Event

What types of crashes are caused by these vehicle defects? The next two pages contain the cross-tabulation for the most harmful events for each of the passenger vehicle types.

#### 3.5 C023 Manner of Crash

The following presents a summary of the Manner of Crash for passenger car vehicle defect crashes. It gives insight especially into those crashes that did not involve just a single vehicle. The top three in the table below are over-represented, but Head-On (front to front only) has almost identical proportions (2.15% and 2.14%) for the vehicle defects and the control group. All of the other items are under-represented, meaning that the control subset (crashes not involving vehicle defects) have proportions that are greater than those of defective vehicles.

#### **3.6 C011 Highway Classifications**

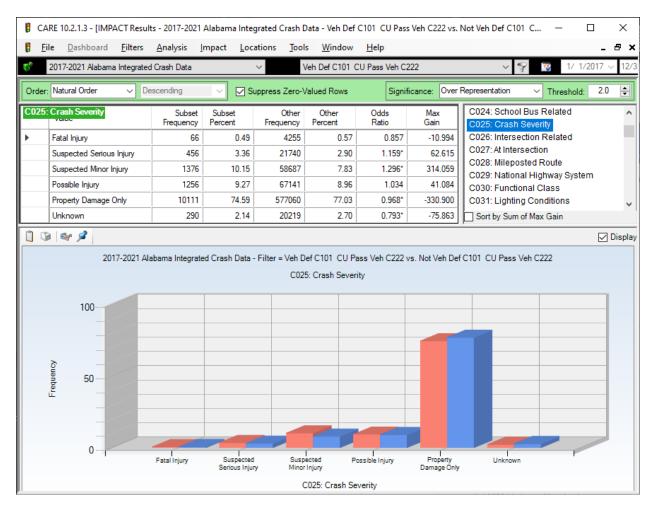

All other things being equal, it is expected that each Highway Classification will have the same proportion of defective vehicle crashes as the defective vehicles traveling on it over the course of the study. This distribution varies sharply from that of large trucks, especially in the Municipal road category. While Interstate highways still show close to twice (1.706) the expected proportion, the proportion of total vehicle defect crashes in Interstate highways is 19.21% for passenger cars, while it was over twice that at 50.36% for large trucks. See the cross-tabulation below for one potential cause of tire problems.

#### 3.7 C222 Vehicle Defects by C224 Impact Speed

Tire blowouts and tread depth issues tend to occur at higher speeds, as shown in the following cross-tabulation of impact speeds by vehicle defect. This accounts for their increased occurrence on higher-speed roadways (e.g., Interstates). It also accounts for their increased severity, which is covered in the next section.

## 3.8 C025 Crash Severity

The severities of vehicle defect crashes are not nearly as reduced (comparatively speaking) with the passenger car subset as we saw they were with large trucks. The difference in Fatal Injury is not statistically significant, and the increases in both Suspected Serious Injury and Suspected Minor Injury types are significantly higher in proportion than what is expected from the non-vehicle-defect group. To analyze this attribute further, a cross-tabulation was run that analyzed the various severity levels by the vehicle defect type, as given below.

#### 3.9 C222 Vehicle Defects by C025 Crash Severity

Clearly tire issues are the major factors for both severe injury and deaths. The two tire defects are quite different in the way that they cause crashes. Tire Blowout/Separation is quite intuitive in the way it would cause a loss of control. Improper Tread Depth, however, would usually have other contributing factors, such as a wet road surface, speed, or both to result in the loss of control. No doubt, tire issues rise to the top concern of passenger car crashes. Brake defects are a distant second priority, albeit with a much higher overall frequency (5,891 for brakes, as compared to the tire issues of 2,670 for blowouts, and 1,608 for tread depth).

	0	1997		2002		2007		2012 2017
		1557		2002	C208- CU M		4	2017

All years with less than100 crashes were removed. The significant over-represented model years are from 1993 through 2006. It is reasonable to expect that older vehicles would have more problems in this regard. However, the maximum year is 2005 with 926 Vehicle Defect crashes.

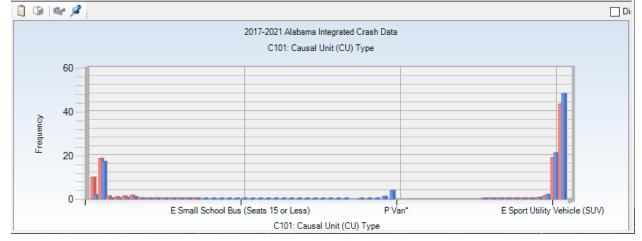

#### 3.11 All Vehicles Tire Issues Further Analysis

The passenger car vehicle defect highest killer was in tire issues. Over five years there were 2,670 crashes caused by blowouts/tire separation, and 1,608 crashes caused by tread depth issues over the five years of the study (4,278 total for tire issues). While the cross-tabulation in Section 3.9 indicates that tread depth was a higher cause of death with 40, as opposed to blowouts, which had 16, there is no implication that the difference between these two numbers is statistically significant. The 56 tire defect fatal crashes resulted in a total of 73 fatalities (14.6 fatalities per year).

These two tire issues account for almost 85% of the passenger car vehicle defect fatalities, and the next highest (brakes) had only about 7.58%, with the remaining being distributed one-each among the other attribute values. It is clear that tire issues are head and shoulders over all other vehicle defect issues when it comes to passenger car fatalities.

This being the case, a subset was formed of the 5,161 defective tire cases (for all vehicles, including large trucks) in an effort to flush out the demographics and focus in on the source of the tire problems. A listing of the causal units included is given in the display on the next page. The number in the Subset Frequency column is the number of tire-related crashes that each of these units had over the five years of the study.

	Suendaria Solution								
	0	Fatal Injury	Suspecte Serious Inj		pected F	Possible Injury	Property Damage Onl	Unknown	
			Serious Inj		C025: Crash S	everity	Damage Ohi	7	

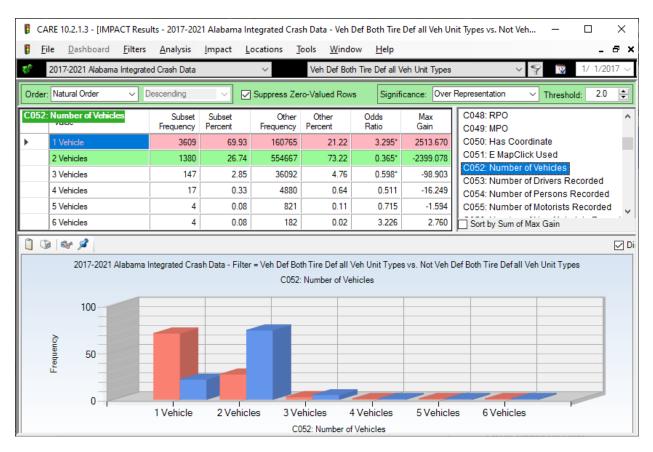

Notice that the proportion of Fatal Injury for the Vehicle Defect crashes (1.36) is over twice (2.417 times) what it is for the non-vehicle-defect control crashes. The two highest injury categories are also over-represented significantly higher than expectation (Odds Ratios 1.875 and 1.449). Thus, we can conclude that these are not minor problems, and something should probably be done to address them, if nothing other than a PSA concentrating on tire defect issues.

## 3.11.2 C015 Primary Contributing Circumstances

The following comparison for Primary Contributing Circumstances indicates that tire problems are usually coupled with another fault related to speed in order to create the crashes.

Frequency								
	U I	Failed to Yield to Pedestrian ir		C015: Prim	-	I or Load Shift		E Fatigued/Asleep

The vast majority of these crashes are single vehicle, as shown by the next display.

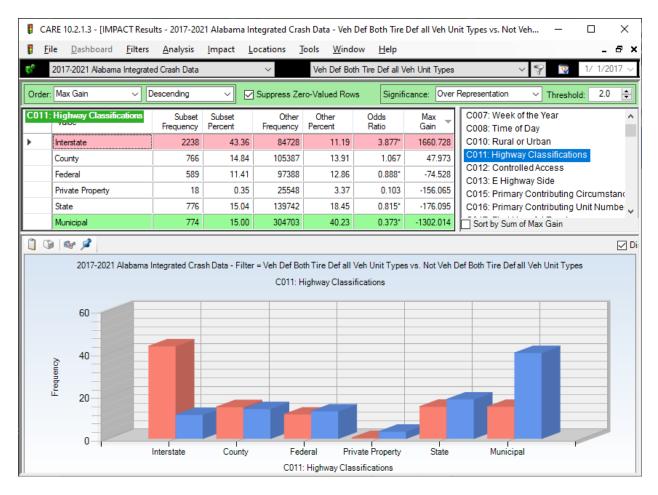

#### 3.11.3 C052 Number of Vehicles (involved in these crashes)

Impact speeds for these crashes is relatively high, further reinforcing the speed cofactor, and as would be expected, they occur more in open country (rural areas).

#### 3.11.4 C224 Estimate Speed at Impact

Speed at impact is a major factor indicating that the problem with tire defects are further compounded by excessive speeds.

#### 3.11.5 C011 Highway Classification

County roads are about as expected (neither over- nor under-represented) perhaps because it is difficult to travel these roads at too high a rate of speed. Federal and State roads are under-represented in favor of Interstates (as are Municipal roads).

Summary of other findings. The causal unit model year follows about the same as given above in Section 3:10, with the older vehicles (up to 1993 for this subset) being over-represented. Driver ages that are over-represented are those from 18-30 years of age. Wet roadways have over twice their expected number of crashes (we suspect that further analysis will show this coming from the low tread tires as opposed to the blowouts). Males are over-represented by about 33% higher proportion than expected. While day of the week is close to the DUI pattern (over-representations on weekend days), the time of day favors the two or three hours before the typical rush hours.

# 4.0 Discussion on Potential Inspection System for Alabama

Most of the promotion of vehicle inspection systems within the states has been conducted in isolation. If you consider the loss of one life and multiply it over the five-year death toll of 70 fatal crashes (14 per year), the cost of implementing a vehicle inspection system is indeed costbeneficial. If we had *certain knowledge* that even one fatality could be saved, unlimited resources would be justified. But no such certain knowledge exists.

What is rarely considered is the downside of any proposed expenditure. Please see general considerations for traffic safety investments that is given under the title of "Considerations for Optimal Traffic Safety Allocation" linked to here:

#### http://www.safehomealabama.gov/wp-content/uploads/2019/03/Traffic-Safety-Innov-2017-04.pdf

The failure is one of not seeing the effect that saving these 14 lives per year (or whatever savings traffic safety professionals might estimate) is going to have on failing to save even more of the total fatalities (close to 1,000 fatalities per year averaged over the last decade). Advocates (in all areas) often fail to see the downside of their actions. As a result, the consumption of traffic safety resources rarely if ever produces the maximum savings of fatalities. Most traffic safety countermeasures have several downsides, but one that is always present is the zero-sum game of the total safety budget, which any given program requiring resources must deplete.

So, for example, if a given countermeasure costs \$100,000 per year these dollars will have to come from other traffic safety programs. It is not a matter of going to the general fund; and even if it were, the same argument could be made: i.e., that this \$100k should go to a countermeasure that has a higher benefit to cost ratio.

The cost of most countermeasures is fairly easy to obtain; however, the benefits that any one of them will produce is highly speculative, and we must turn to the traffic safety professionals to estimate these benefits. There are a number of resources to this effect available from NHTSA e.g., *Countermeasure that Work:* 

https://www.nhtsa.gov/sites/nhtsa.gov/files/2021-09/Countermeasures-10th\_080621\_v5\_tag.pdf.

Few studies of effectiveness have been performed for vehicle inspection systems for a variety of reasons. But the major issue is in isolating the number of crashes that will be reduced by implementing the program. "The program" itself is not at all defined, since there are variations in every state that has "implemented a program." So it is impossible to aggregate the results.

Please review the findings above. Recognize that large truck inspections are handled already by FMCSA mandates. In essence, they already have an inspection system. So, we are mainly talking about the second half of the findings given above – those for passenger cars. The major problem with passenger cars was found to be tires. Further analyses can and should be done if programs to address this problem are to be developed. This can easily generate the target groups

and the demographics that should be employed to develop the most effective tire countermeasure program.

The big question that must be answered: is a full scale inspection system necessary to deal with the issue of car tires. Could one be developed that just concentrated on these issues and perhaps the third item, which was brakes? Would a PI&E program be just as (perhaps more) effective, but at a fraction of the cost? Could tire providers be involved in not repairing tires that are prone to be defective?

We are not prepared to answer these questions at this point; but we feel that raising them is sufficient to getting decision-makers moving in the right direction. We urge decision-makers to consider how many lives might be saved if the cost of implementing an inspection program were to be invested in other more cost-effective countermeasures. We stand ready to provide additional information from crash records to help them if they feel that such an effort would be warranted.

For more information on this subject from NHTSA and other sources, please see: http://www.safehomealabama.gov/tag/defects-recalls/
